(54) Title: DETECTION AND QUANTITATIVE DETERMINATION OF RNA AND DNA

(57) Abstract

The method for the detection and/or quantitative determination of target RNA or DNA in an analyte sample includes the steps of: a) contacting the analyte with magnetic particles carrying a single stranded 5'-attached DNA probe capable of binding to said RNA or DNA; b) contacting the magnetic particles with an aqueous solution of a reverse transcriptase or polymerase in the presence of labelled nucleotides using the probe as a primer whereby labelled complementary single stranded DNA is formed if said RNA or DNA was present in said analyte; magnetically aggregating the magnetic particles onto a surface and removing said solution; and c) detecting the presence or absence of said label and/or determining the amount of said label. The chain length of complementary single stranded DNA is limited by, for example a predetermined amount of dideoxynucleotides being present at step (b) to limit chain synthesis to a predetermined average length or the probe binding to said DNA or RNA a predetermined distance from a chain terminating point of said DNA or RNA. A kit for performing the method is disclosed.

Detection and Quantitative Determination
of RNA and DNA

5

This invention relates to the detection and quantitative determination of RNA and DNA and to kits for performing such assays.

DNA and RNA may be detected and/or assayed by a 5 number of conventional techniques using solution and/or supported reactions. In general, a specific DNA or RNA sequence is isolated from a sample by electrophoresis or diffusion on to a support such as a nitrocellulose membrane-filter and then a labelled probe, which 10 selectively hybridises only to a target nucleic acid, is added to the support. A common type of probe is single stranded (ss) DNA complementary to a sequence in the target DNA or RNA.

The hybrid molecule so formed may then be detected 15 by a variety of techniques depending on the nature of the label used. An example of such a hybridisation system is US Patent No. 4,358,535 of Falkow *et al.*

One method of labelling a probe is to incorporate a radioactive atom such as ^{32}P , ^{14}C or ^3H , e.g. by the 20 nick translation method of Rigbny *et al* (J. Mol. Biol., 113:237, 1977) whereby a labelled nucleotide is incorporated into a gap created in the DNA of the probe. Other labels can be introduced by nick translation, for example by incorporating biotinylated nucleosides which 25 can then be coupled to an avidin bound label such as an enzyme. The DNA can also be labelled with antigenic groups reacting with antibodies.

For assay or quantification of nucleic acids, e.g. 30 DNA or mRNA, either the total nucleic acid material present in a sample or that transcribed from a specific gene, is conventionally determined by the so-called dot-blot analysis technique. In this technique a suitable

probe, labelled for example with ^{32}P or ^{35}S is hybridised onto a membrane filter carrying dots of the sample nucleic acid at varying dilutions together with dots of reference nucleic acid at varying known dilutions.

5 After autoradiography, the intensity of the sample dots may be compared visually or by a densitometer with the reference dots to give an estimate of the concentration of the nucleic acid.

Nucleic acids are often present in quantities which 10 are too small to be assayed by conventional dot blotting and may often advantageously be amplified by the PCR (Polymerase Chain Reaction) technique. In the case of DNA, the unamplified dsDNA is denatured and primers are annealed to both the coding and the non-coding strand.

15 The primers are preferably those corresponding to the 5'-terminal sequences of the DNA so that on extension of the primer with a polymerase, the whole DNA sequence of each strand will be replicated. If, however, the intended assay requires hybridisation of a labelled

20 probe only to a central sequence of the DNA, it will be adequate for the primers to hybridise to sites on either side of that section so that transcription produces copies of shorter DNA sequences including the hybridisation site of the probe. The double stranded

25 DNA so produced is then denatured by raising the temperature followed by rapid cooling. An excess of the primer molecules is present and are annealed to the newly formed coding and non-coding strands. Extension using polymerase produces further double stranded DNA.

30 The temperature cycling can be repeated many times, thereby producing a large number of copies of the DNA. Preferably, the polymerase used is one which can withstand the highest temperature of the cycle, commonly the Taq polymerase, otherwise there is a need to

35 separate the polymerase from the nucleic acids before each heating step or replenish the polymerase after each cooling step. Both the latter options are expensive and

add to the complexity of the technique.

Even with the advance made by the use of PCR a worker still needs to fix the target DNA to a support during the step of hybridisation to the labelled probe 5 so that it can be immobilized during washing steps e.g. to remove unbound labelled probe. Usually the fixing is non-specific, especially when using nitrocellulose filters, and one often finds background labelling due to the probe becoming non-specifically fixed to the 10 support.

It has been suggested, e.g. in US 4672040 (Advanced Magnetics) and EP 265244 (Amoco Corp.), that magnetic particles may be used as supports for DNA probes.

There is a need to provide a method for the 15 detection and/or quantitative determination of RNA or DNA which overcomes the difficulties which exist with prior methods. It is an object of the invention to meet this need.

Accordingly, the invention provides a method for 20 the detection and/or quantitative determination of target RNA or DNA in an analyte sample which includes the steps of:

- a) contacting the analyte with magnetic particles carrying a single stranded 5'-attached DNA probe capable 25 of binding to said RNA or DNA;
- b) contacting the magnetic particles with an aqueous solution of a reverse transcriptase or polymerase in the presence of labelled nucleotides using the probe as a primer whereby labelled complementary single stranded 30 DNA is formed if said RNA or DNA was present in said analyte to serve as template; magnetically aggregating the magnetic particles onto a surface and removing said solution; and
- c) detecting the presence or absence of said label 35 and/or determining the amount of said label.

It is one advantage of this invention that labelling takes place using standard labelled

nucleotides rather than a labelled probe, the probe in this case serving the triple function of selecting the target nucleic acid, immobilising the latter for ease of separation from unbound label and serving as a primer.

5 This is particularly advantageous when radioactive labels are concerned since it is not necessary for the probe to be labelled as a preliminary step thereby leading to a delay which may reduce the activity of the label by radioactive decay. A further advantage is that
10 the radioactive signal polymerised onto the primer on the beads can be directly analysed on a scintillation counter, avoiding long autoradiograph exposure times. The method is characterised by its simplicity and rapidity as compared to previous techniques of nucleic
15 acid assay.

The term "label" as used herein is intended to encompass both direct labels, such as radioactive elements, fluorophores and chromophores, as well as indirect labels where a low molecular weight ligand of a
20 specific binding pair is attached to a nucleotide and thus serves as an attachment for a label. Examples of such indirect labels and specific binding pairs include biotin, which can be affinity bound by avidin or streptavidin and haptens which can be affinity bound by
25 antibodies or binding fragments thereof. The larger binding partner may not, in itself, be a label but may have a label, such as an enzyme, latex bead, fluorophore or chromophore attached thereto.

30 Clearly, it would be expensive to label a whole gene or large portion thereof. Accordingly, it is a preferred feature of the invention that the chain length of complementary single stranded DNA is limited. This feature may be achieved, for example, by the addition of some dideoxy nucleotides during the labelling
35 polymerisations to limit the chain length of the labelled cDNA which is synthesised.

Where the sequence of the target nucleic acid is

known, it is possible to synthesise a defined cDNA chain by omitting one or more of the labelled nucleotides so that synthesis stops at a known point. It is possible in such cases to use a single labelled nucleotide where 5 this would produce sufficient attached label for detection.

Furthermore the ratio of dideoxy nucleotides to other nucleotides controls the average length of the cDNA chain and thus the average number of labelled bases 10 hybridised to each molecule of target nucleic acid. If the number of labels on each target molecule is known either precisely or as an average, the total signal divided by the signal from one label multiplied by the above known number of labels gives a direct indication 15 of the number of molecules of target nucleic acid.

Another method of introducing a known number of labels is to design the probe to hybridize to a sequence of the target nucleic acid which is spaced from the 5' terminus by a known number of bases. Reaction with 20 labelled nucleotides and a polymerase thus incorporates a precisely known number of labelled bases.

In yet another method of limiting chain length, when dealing with assays for mRNA, one can provide a poly-dT probe of sufficient length to bind polyA "tails" 25 and serve as a primer yet it is shorter than the polyA "tails". After hybridisation, a polymerase and thymidine are added, at least some of the thymidine being labelled, and a complementary labelled polyT cDNA is produced which extends from the end of the primer to 30 the first non-adenyl residue of the mRNA. This qualitative method can be quantitative if one knows the lengths of the poly-dT probe and the polyA "tails" and one determines statistically the average length of cDNA which will be produced. The signals from each cDNA can 35 be readily determined on the basis of the ratio of labelled: non-labelled thymidine.

The method according to the invention can

advantageously include PCR amplification of the target nucleic acid between steps (a) and (b). Where the nucleic acid is mRNA, this can be bound to magnetic particles carrying oligo-dT probes and reacted with 5 reverse transcriptase to produce cDNA. The non-coding strand is then synthesised using a polymerase. The dsDNA so produced can then be denatured and the coding and non-coding strands hybridised to specific DNA probes attached to magnetic particles, these probes serving as 10 the primers for PCR amplification using a suitable polymerase. If an excess of the magnetic particles separately carrying the two specific DNA probes/primers is present, to hybridise to the cDNA strands as they are produced, the PCR temperature cycle can be applied and 15 repeated until adequate amplification has been effected. The final step of PCR amplification should be denaturation to produce the single stranded DNA for the labelling reaction.

Particular uses of the method of the invention 20 include:

1. Detection and/or quantification of a specific DNA sequence using magnetic particles with a specific probe, for example in detecting the presence of specific viruses or bacteria in body fluids or contaminated food, 25 or detecting genomic genotypes in human diagnosis, (optionally with PCR or other amplification).
2. Quantification of total cellular mRNA using magnetic particles with an oligo-dT probe, for example in small scale purifications.
- 30 3. Detection and/or quantification of a specific mRNA sequence using magnetic particles with a specific probe, for example in studying gene expression, especially levels of gene activity (e.g. oncogene transcription levels in cancer diagnosis) and detection of viruses 35 such as HIV which are integrated in cell genomes or free in the cells.
4. In addition to isolating the target mRNA or DNA

having the magnetic particles, this can be directly assayed by incorporating labelled nucleotides into an aliquot of the isolated nucleic acid using the same magnetic probe (and a polymerase or reverse transcriptase) so that the label can provide a direct determination of the target DNA or RNA isolated.

Several advantages of the use of magnetic particles stand out clearly. The magnetic particles can be added to a mixture containing the target nucleic acid, e.g. a cell extract, stirred and then magnetically drawn to one side of the receptacle. The liquid can then be removed together with unwanted components and the magnetic particles, having the RNA bound thereto, can then be redispersed in a washing solution. The washing step can be repeated several times in quick succession. The whole process of obtaining the target nucleic acid can be performed in under 15 minutes.

A further advantage is the ease with which hybridisation or any process effected using the magnetic particles can be continuously monitored by magnetically aggregating the particles at intervals and assaying a label associated either with the material on the particles or with material in the supernatant.

The use of magnetic aggregation to separate the particles is far less vigorous than traditional separation techniques such as centrifugation which generate shear forces which can degrade nucleic acids or proteins.

The use of magnetic aggregation to separate the particles is far less vigorous than traditional separation techniques such as centrifugation and thus high shear forces which can degrade nucleic acids or proteins are avoided. Moreover, the ease with which the magnetic particles can be separated from solution and redispersed in a different solution lends itself especially to automation, in particular in automated synthesis or assay methods.

As indicated above, the probes can be DNA moieties which will hybridise with RNA or DNA. These include oligo-dT, which will hybridise with the poly A 'tails' universally present on native mRNA, and probes 5 comprising specific DNA sequences which hybridise with specific sequences in target DNA and RNA molecules. Each probe may consist of a directly attached single stranded DNA which may be oligo-dT or a specific DNA sequence or it may be attached to the magnetic particle 10 via a double stranded piece of DNA.

Where the method of the invention is applied to the detection and/or quantification of all the mRNA material from a cell lysate, the probe is advantageously oligo-dT, that is a relatively short chain of 15 deoxythymidine units, e.g. from 20 to 200 bases. Such a chain may be readily and cheaply prepared by enzymic polymerisation of deoxythymidine units, e.g. from 20 to 200 bases. Such a chain may be readily and cheaply prepared by enzymic polymerisation of deoxythymidine.

20 The oligo-dT probes may be directly attached covalently to the beads. It may be advantageous to attach the probe to the bead via a linker sequence comprising a restriction endonuclease (RE) specific site, so that the probe and hybridised DNA or mRNA can, 25 if desired, be liberated into solution by mild enzymatic reaction. In the conventional detection and quantification methods particularly when automated, the enzymic operations are carried out in the same unchanged buffer which is thus not optimised for each reaction.

30 However, using magnetic particles according to the invention allows one to change buffers and the like and thereby optimise the production of cDNA. Further, in the case of ss cDNA synthesis, the ratio of nucleotide reagents to mRNA is usually kept approximately 35 stoichiometric in order to avoid contaminating succeeding stages with excess reagent. The ease and speed of washing, which comes from the use of magnetic

particles according to the invention, permits excess reagents to be used, with a consequent increase of efficiency.

To avoid random hybridisation of unwanted nucleic acid and to complete the removal of the remaining components of the hybridisation solution, the magnetic particles are preferably washed at least once after the initial magnetic separation. To remove nucleic acid bound by random partial homology, the washing may be carried out under stringent conditions, either by increasing the temperature or by using a lower salt concentration than that used in hybridisation, e.g. 0.5M sodium chloride or an equivalent solution.

Stringency is normally calculated according to the probe length and G:C content. If the homology between the probe oligonucleotide and the target nucleic acid is inexact, washing should be carried out under less stringent conditions. In general, washing should be carried out at a temperature 12°C below the melting temperature of the duplex (T_m). The approximate T_m may be conveniently calculated according to the following relationships (taken from Maniatis, T. et al (1982) Molecular Cloning; a laboratory manual pages 388-389).

(a) $T_m = 69.3 + 0.41 \cdot (G+C)\% - 650/L$

25 L equals the average length of the probe in nucleotides.

(b) The T_m duplex DNA decreases by 1°C with every increase of 1% in the number of mismatched base pairs.

(c) $(T_m)u_2 - (T_m)u_1 = 18.5 \log_{10} \frac{u_2}{u_1}$

30 where u_1 and u_2 are the ionic strengths of two solutions.

For small oligonucleotides, the melt temperature may be approximated in degrees centigrade as follows:

35 $T_m = 2 \times (\text{number of A+T residues}) + 4 \times (\text{number of G+C residues})$

10 The hybridisation reaction is preferably effected in a 1M sodium chloride solution or an equivalent solution known in the art. (See Nucleic Acid Hybridisation, B D Hames and S J Higgins, IRL Press, 1985).

5 In one embodiment of the invention the probe is isolated by hybridisation to the poly A tails present on oligo-dT and all the mRNA in a cell extract can thus be

10 advantage of this embodiment is that attachment of the oligo-dT DNA probe to the bead via its 5' terminus, allows the probe to also serve as a primer for reverse transcription not only to incorporate labelled bases in accordance with the invention but, using the same

15 magnetic probe, to synthesize ssCDNA. Such synthesis is more fully described in our copending application of the even date herewith claiming priority from United Kingdom Patent Application No. 8827158.0.

20 The target nucleic acid may require an initial treatment step before performance of the method according to the invention. For example, if the target nucleic acid is dsDNA an initial melting step followed by rapid cooling will be necessary so as to provide ssDNA. (Determination of the melt temperature T_m is discussed above). If it is desired to assay a

25 particular mRNA from a pool of mRNA then, due to the lower stability of RNA compared with DNA it may be preferable to first synthesize cDNA for all mRNA species in the pool before selecting the target nucleic acid with the specific probe. If the target nucleic acid is of relatively low abundance then it is preferable to amplify it using PCR if, of course, two spaced specific sequences are known.

30 It is clear that the initial step of mRNA selection is much simpler in the process according to the invention since a specific probe is used to isolate a particular mRNA and the mRNA size fractionation and identification stages of the prior art are not

necessary, thus avoiding lengthy delays and consequent mRNA degradation.

In the conventional process of mRNA isolation and purification, successive enzymic operations are carried out in the same vessel; by products being precipitated at each stage with ethanol and the enzyme being removed by phenol extraction at each stage. This makes it difficult to optimise the conditions for each reaction. In the present method, due to the ease of separation of the magnetic particles from the supernatant, an optimal buffer can be used at each stage.

A particularly useful form of probe for use where subsequent cDNA synthesis is intended is a DNA sequence in which the 3' end overlaps and is hybridised to a region near the 5' end, leaving the remainder of the 5'-terminal region as a sticky end to hybridise with the target nucleic acid. If a functional group such as an amino group is present in a position distal from the sticky end, the loop may be covalently attached to the magnetic particle e.g. via carboxyl groups.

Alternatively, a biotin group may be attached to the loop and thus bind the probe to streptavidin coated particles. DNA having a terminal region corresponding to the sticky end will thus have the possibility of being ligated to the adjacent part of the loop if it is required to secure the DNA covalently. RE sites can be provided in the overlap region of the probe for subsequent detachment of the DNA.

The use of specific DNA probes coupled to magnetic particles is of particular value in detection and quantification of families of mRNA molecules having a common sequence hybridising to the probe. Thus, for example, the mRNA coding for immunoglobulin may be assayed from a relevant cell extract using DNA probes from the constant regions of the heavy and light chains.

In the study of genetically transmitted diseases, it is possible to assay mRNA corresponding to a series

of modified genes using a probe corresponding to a conserved sequence of the gene and to synthesise the corresponding DNA of the genes using the methods described above.

5 The probe oligonucleotide may be prepared by using any of the commercially available DNA synthesis devices, e.g. those available from Applied Biosystems, Inc. (850-T Lincoln Center Drive, Foster City, CA 94404).

10 The particles are particularly advantageously monodisperse and/or superparamagnetic. Both these properties greatly assist the kinetics of reactions in which the particles are involved. It is a surprising feature of the invention that the probes carried by the particles react in the reactions virtually as rapidly as 15 if free in solution. Thus, as mentioned earlier, total isolation of mRNA for example can be effected in about 15 minutes in contrast with the 2 hour period using an affinity column. By using monodisperse particles, that is particles of substantially the same size, the 20 reaction rate and other parameters are particularly uniform. By using superparamagnetic particles (that is particles containing sub-particles of ferromagnetic material which are smaller than the domain size required to maintain permanent magnetism), one can avoid magnetic 25 aggregation or clumping of the particles during reaction, thus again ensuring uniform and rapid reaction kinetics. The particles can be readily aggregated onto a surface by application of a magnetic field and then be readily re-dispersed for a subsequent treatment step, 30 e.g. by physical agitation.

The preferred magnetic particles for use in this invention are monodisperse superparamagnetic beads produced according to EP 83901406.5 (Sintef), the disclosure of which is incorporated herein by reference. 35 In these beads, the iron is very uniformly distributed and provides a very uniform response to a magnetic field which is important in designing a reproducible

procedure, particularly for automation, since all the beads move at the same speed. Furthermore, since a reproducible amount of iron can be incorporated in each particle, this can be adjusted to a relatively low level 5 which permits the specific gravity of the particles to be in the range specified below. In the case of prior, less regular products, small particles either had too little iron to counteract Brownian forces when a magnet was applied or the specific gravity of the material led 10 to undesirable sedimentation of the larger particles. Some automated systems use magnetic fields to restrain the particles within a reaction zone while solutions are passed through; uniform magnetic and rheological properties are essential in magnetic particles for use 15 in such a system.

The term "monodisperse" used herein is intended to encompass size dispersions having a diameter standard deviation of less than 5%.

We prefer to use beads having a specific gravity in 20 the range 1.1 to 1.8 most particularly 1.2 to 1.5. In the monodisperse beads used in accordance with the invention, the specific gravity is, again, particularly uniform, leading to uniform and predictable kinetic characteristics.

25 Advantageously, the monodisperse particles are spherical beads of diameter at least 1 and preferably at least 2 microns, being preferably not more than 10 and more preferably not more than 6 microns in diameter e.g. about 3 microns. Smaller particles sediment more slowly 30 and in some cases the sedimentation time may be long compared to the reaction time, thus avoiding the need for physical agitation. However, particles of mean diameter 0.1 to 1.5 microns including fine particles of much smaller diameter, as used in the prior art, behave 35 unreliable in response to magnetisation.

The attachment of the probes to the particles may be by direct chemical bonding as well as affinity

binding, by streptavidin/biotin complexes and the like.

For attachment of the probes, the magnetic particles may carry functional groups such as hydroxyl, carboxyl, aldehyde or amino groups. These may in general be provided by treating uncoated monodisperse, superparamagnetic beads, to provide a surface coating of a polymer carrying one of such functional groups, e.g. hydroxyl groups, a polymer or copolymer of acrylic acid or methacrylic acid to provide carboxyl groups or an aminoalkylated polymer to provide amino groups or an hydroxyl groups, together with a polyglycol to provide

14
10
15
20
25
30
35

Patent No. 4654267 describes the introduction of many such surface coatings.

Preferred coated particles for use in the present invention may be prepared by modification of the beads according to the US Patents 4336173, 4459378 and 4654267, the disclosure of which is incorporated herein by reference. Thus, for example, macroreticular porous polymer particles, prepared from styrene-divinylbenzene and with a diameter of 3.15μm were treated with HNO_3 to introduce $-\text{NO}_2$ groups at the surface of the pores. Then the particles were dispersed in an aqueous solution of Fe^{2+} . The Fe^{2+} is oxidised by the $-\text{NO}_2$ groups. Then leads to precipitation of insoluble iron oxy-hydroxy compounds inside the pores. After heating the iron exists as finely divided grains of magnetic iron oxides throughout the volume of the porous particles. The NO_2 groups are reduced by the reaction with Fe^{2+} to NH_2 groups.

To fill up the pores and to introduce the desired functional groups at the surfaces, different monomers are caused to polymerize in the pores and at the surface. In the case of a preferred type of particle,

through polymerization of methacrylic acid.

Thus, for example, the NH₂ groups initially present in the beads may be reacted with a diepoxyde as described in US Patent No. 4654267 followed by reaction with methacrylic acid to provide a terminal vinyl grouping. Solution copolymerisation with methacrylic acid yields a polymeric coating carrying terminal carboxyl groups as in R452 beads referred to below.

Similarly, amino groups can be introduced by reacting a diamine with the above product of the reaction with a diepoxyde as in the R240, R442 and R469 beads, while reaction with a hydroxylamine such as aminoglycerol introduces hydroxy groups as in the M450 and L255 beads.

Dynabeads M450 (diameter 4.5 microns) which may be obtained from Dynal, Oslo, Norway have been coated with a monomeric epoxide, resulting in a mixture of epoxy and hydroxy groups. Contact with water however, converts the epoxy groups to hydroxy groups.

Dynabeads M-280 (diameter 2.8 microns) are polystyrene beads having hydroxyl groups which have been converted into tosyloxy groups by reaction with p-toluene sulphonyl chloride.

Using functionalised coatings of the above types, we have found the non-specific binding of DNA and/or RNA to be very low, particularly in the case of the carboxylated beads.

As indicated above, the probe and RE linker are preferably attached to the magnetic particles via carboxyl groups, the DNA being firstly provided with a 5'-terminal amino group which can be made to form an amide bond with the carboxyl using a carbodiimide coupling agent. 5'- attachment of DNA can also be effected using hydroxylated magnetic particles activated with CNBr to react with 5'- amino DNA.

The 3'-attachment of the oligonucleotide DNA can also be effected by chemical synthesis. Here again, the very uniform nature of the monodisperse particles

provides uniform reaction rates particularly suited to synthesis in an automated synthesiser such as the Gene Assembler (Pharmacia AS). The magnetic particle needs to be provided initially with a hydroxyl or protected hydroxyl group. Dynabeads M-280 of Dynal A/S are well suited to this purpose. If necessary, however, other surface functions such as carboxyl could be used to attach a linker carrying a hydroxyl group or alternatively a 3'-attached nucleotide.

10 5'-Attachment may be effected by coupling of 5'-amino-oligonucleotides to tosyl-activated magnetic particles. The latter may be produced by tosylation of hydroxylated magnetic particles such as Dynabeads M-280 of Dynal A/S. Displacement of the tosyloxy group leaves 15 the 5'-amino group directly attached to the magnetic beads.

20 Since biotin labelled nucleotides are commercially available, the 3'- end of DNA fragments can be labelled using DNA polymerase and these may be conveniently bound to avidin or streptavidin attached to the magnetic particles e.g. via a hydroxy group. The biotin label may be attached to the nucleotide by a spacer arm, such as one or more ϵ -aminocaproic acid moieties, to minimize steric hindrance.

25 In general, the functionalisation of the beads and subsequent attachment of probes is advantageously such that each magnetic particle carries 10^3 - 10^6 probes. (1-300 pmols per mg). The uniform size of the magnetic particles is of advantage in ensuring uniform probe density when the probes are reacted with the particles. Uniform probe density is important in ensuring that all the probes behave in substantially the same way in the

various procedures in which they are used.

It is a remarkable feature of the magnetic particles that enzyme activity appears to take place very close to the particle surface e.g. within 7 bases.

5 Thus, if an RE site is present in a linker sequence as discussed hereinafter and if the probe is subsequently used as a primer, it is found that sscDNA and hence ds cDNA can be synthesised by the DNA polymerase past the RE site towards the bead surface and can thus itself
10 readily be cleaved by the appropriate endonuclease. In the case of the carboxylated beads, it is found that the micro-surface of the beads is extremely irregular, presenting an unusually large surface area which may
15 reduce steric hinderance to hybridisation and enzyme activity close to the surface. On the other hand the non-specific binding to such carboxylated beads is not increased.

According to a further feature of the invention we provide a kit for the detection and/or
20 quantitative determination of target RNA or DNA comprising

- (a) magnetic particles carrying single stranded 5'-
attached DNA probe, and one or more of the
following:
- 25 (b) a reverse transcriptase
- (c) a polymerase
- (d) labelled nucleotides
- (e) appropriate buffers.

30 The following examples are given by way of
illustration only:-

Example 1(a)

Carbodiimide (EDC) mediated attachment of 5' -NH₂ probes
to carboxyl beads.

35 (a) The reaction used for attaching probes to carboxyl beads is as follows. Amino groups introduced at the 5'-end of the probes using a one-step reaction method

described by Chu *et al.* (Chu, B.C.F., and Orgel, L.E. (1985) DNA 4, 327-331.), results in a greater nucleophilicity of the terminal primary amino group of the alkyl linker as compared to the amino 5 functionalities of the bases. It was therefore expected that the carboxyl groups on the beads would react preferentially with these primary amino groups.

100 ug 5'-NH₂ modified probe in 600 ul of 0.1 M imidazole-buffer pH 7, 0.1 M EDC were added per mg of 10 R452 carboxyl beads. The reaction mixtures were incubated for 20 hours at room temperature with gentle shaking.

(b) NH₂ modified probes were made using Applied Biosystem synthesizer and Aminolink II.

15 The coupling reactions were as follows:

10 μ g 5'-NH₂ modified probe in 100 μ l of 0.1M imidazole buffer pH 7.0, 0.1M EDC was added per mg of R452 carboxyl beads. The reaction mixtures were 20 incubated for 20 hours at room temperature on a roller mixer (Coulter) followed by washing in TE buffer containing 0.1M NaCl (4x).

Hybridization efficiency:

25 A range of beads with different amount of probe attached were tested in hybridization experiments with a complementary 25 mer polydT probe.

The beads covered the range 1-250 pmol probe attached per mg beads.

30 Increasing amounts of 25 mer polydA oligonucleotide hybridized with increasing amounts of probe attached. 193 pmol hybridized to beads with 250 pmol attached. However, when the target molecule was in the range of 1000 bp (control mRNA Promega Corporation) there was no difference in hybridization efficiency between the bead 35 with 100 pmol of attached probe compared with the more densely coupled beads.

Example 2Carbodiimide (EDC) mediated attachment of
5'-phosphate-probes to amino beads.

Probes were attached via a phosphoramidate linkage
5 to 3 different amino beads by the method described by
Ghosh *et al.* (Ghosh, S.S., and Musso, G.F. (1987)
Nucl. Acids Res. 15, 5353 - 5372.). The amount of DNA
attached to the different beads varied from 1.4-11.3
micrograms/mg.

10 The R469 beads which carry an amino group at the
termini of an polyethylene glycol linker (8 atoms), bind
a larger amount of probes than R240 beads which carry
the amino group on a shorter linker (3 atoms). when the
linker is made longer (number of atoms 20) as in the
15 case of for the R442 beads, a decrease in the amount of
probes bound to the beads is observed. This is probably
due to secondary structures of the linkers which results
in the terminal amino group becoming unavailable for
coupling.

20 The amount of non-specifically bound DNA varies
among the beads (7-30%) probably according to number of
amino groups per unit of surface area. The R469 beads,
which bind the largest amount of probes covalently (11
ug/mg), showed the lowest non-specific binding.

25 The acid lability of the phosphoramidate bond (Chu,
B.C.F., Wahl, G.M., and Orgel, L.E. (1983) Nucl. Acids
Res. 11, 6513 - 6529.) is used for measuring degree of
end-attachment by acid hydrolysis. The amount
end-attached probes varies between the different beads
30 from 20-65%, and again, the R469 bead seems to be the
preferable one with 65% of the probes end-attached.

35 We were able to attach twice as much probe material
to the R469 beads by performing the reaction in
imidazole buffer pH 7 for 3 hours at 50°C, instead of pH
6, for 24 hours at room temperature. An increase in
molarity of EDC from 0.1 M to 0.2 M resulted in a 20%
decrease in amount of probes on the R469 beads (data not

shown).

General Method

600 pmole (6 ug) of oligo A (36 mer) were dissolved in 1 ml of 0.1 M imidazole, pH 7, 0.1 M EDC and mixed 5 with 5 mg of amino beads, and incubated for 3 hours at 50°C.

Example 3

Coupling of 5'NH₂ probes to tosyl activated beads

10 NH₂ groups were introduced at the 5' end of oligonucleotides using Applied Biosystems DNA Synthesizer 381A and Aminolink II to introduce the primary NH₂ group at the 5' end. Aminolink II is supplied from Applied Biosystems. After synthesis these 15 amino modified oligonucleotides were used directly in the coupling experiment.

Tosyl activated M-280 beads are commercially available from DYNAL AS, Oslo.

20 Coupling procedure:

10 mg of tosyl activated beads were mixed with 50 μ g NH₂ modified oligonucleotide in 100 μ l 0.5M Na₂HPO₄ and incubated at 37°C for 20 hours on a roller mixer (Coulter) followed by washing in TE buffer containing 25 0.1M NaCl (4x).

Example 4

Direct synthesis

30 Dynabeads R 488 beads were used. They are the same beads as M-280 except that the diameter is 3.15 microns instead of 2.8 microns and they contain primary OH groups on the surface as in the M-280 beads.

Using the synthesizer (Pharmacia Gene Assembler) the 3' end of DNA will be attached to the surface.

35 Only small modifications were necessary to fit the 3.15 micron beads. In the standard small scale column from Applied Biosystems teflon filters with cut off at

3.0 microns were installed, the beads loaded and the column assembled.

Since this support does not contain dimethyltrityl (DMTr) groups and this machine stops if no such chemical is released in the first steps in the first cycle, small modifications in the start procedure were introduced. The synthesis was started using a standard ABI small scale column until the DMTr groups were released. Then the Gene Assembler was stopped manually and the modified column with magnetic beads was put into the Gene Assembler. The standard synthesis programme as recommended by the manufacturer was then followed. Deprotection was as recommended by Pharmacia. Direct synthesis was used to produce oligo(dT)₂₅ and the following sequence from the C region of the kappa light chain gene:

5'-TCACTGGATGGTGGGAAGATGGATACAGTTGGTGCA-3'.

Example 5

20 Materials and methods

Magnetic beads

Dynabeads M-280 Streptavidin (Dynal A.S, Box 158, N-0212 Oslo) were used as solid phase. These are monodisperse superparamagnetic polymer particles with a diameter of 2.8 μm covalently coupled with Streptavidin. They have a surface area of 4.3 m^2/g .

Biotin binding capacity

100 μl 6 x SSPE (Standard saline with phosphate and EDTA: Maniatis) containing 1 nmol ¹⁴C-Biotin (Amersham) was added to 0.5 mg beads (prewashed in 6 x SSPE) and placed on a roller mixer (Coulter) at room temperature for 15 minutes.

After two separate washes in 6 x SSPE the fraction of bound ¹⁴C-Biotin was measured by scintillation counting.

Deoxyoligonucleotides

Deoxyoligonucleotides were synthesized on an

Applied Biosystems 381A DNA synthesizer.

Chemicals were purchased from Applied Biosystems.

5' amino modified deoxyoligonucleotides were made using AminolinkII.

5 The immunoglobulin light kappa chain probe used was:

5'-TCACTGGATGGTGGGAAGATGGATACAGTTGGTGCA-3'.

Biotinylation of probes

10 Biotin XNHS ester (Clontec N-succinimidyl of N-biotinyl ϵ -caproic acid) was used as recommended by the supplier.

0.1 μ mol of NH_2 -modified oligo(dT)₂₅ in 90 μ l of water was added 10 μ l labelling buffer (1M sodium bicarbonate/carbonate, pH 9.0) and vortexed.

15 Finally 25 μ l Biotin XNHS ester (100 mg/ml) in dimethylformamide was added and incubated at room temperature overnight.

Excess labelling reagent and buffer was removed in a Sephadex G50 spin column.

20 The 5' Biotin oligo(dT)₂₅ was endlabelled using the fill in reaction by Klenow polymerase, α -[³²P]-dTTP and oligo(dA)₂₅ as template. Excess label was removed using a Sephadex G50 spin column.

Preparation of oligo(dT) Dynabeads (T-beads)

25 200 μ g Biotinylated oligo(dT)₂₅ (24 n mol) in 2.5 ml 6 x SSPE was mixed with 50 mg prewashed Dynabeads M-280 Streptavidin and incubated on a roller mixer for 15 minutes at room temperature.

30 After two washes in 6 x SSPE the beads were stored at 4°C in 6 x TE, 0.1 % SDS.

Oligonucleotide hybridization assay

35 In the standard assay to measure hybridization capacity of different batches of T-beads, 0.1 mg of the beads in an eppendorf tube was washed once with 6 x SSPE, 0.1 % SDS. A magnet rack (MPC-E, Dynal A.S., Oslo) was used to aggregate beads between each step.

After removal of the washing buffer, 50 μ l

hybridization solution (6 x SSPE, 0.1% SDS), containing 50 pmol of oligo(dA)₂₅ with trace amount (1-2 x 10⁵ cpm) α -[³²P]-dATP-labelled oligo(dA)₂₅ was added.

After gentle mixing the tube was left to hybridize 5 for two minutes at room temperature.

The hybridized beads were washed twice with 2 x SSPE, 0.1 % SDS at room temperature and the percentage of oligo(dA)₂₅ hybridized to the oligo(dT)₂₅ Dynabeads was measured in a scintillation counter.

10 Labelling of poly A mRNA tracer

1 μ g 1200 bp mRNA with a 3'polyA₃₀ tail (Promega) was mixed with 2.5 pmol oligo(dT)₂₅ in 10 μ l 5 x Klenow buffer, 1 u RNasin (Promega), 10mM DDT. After two minutes at room temperature 10 μ Ci α -[³²P]-dATP, 1 u Klenow polymerase (Amersham) and water up to 50 μ l were added and incubation continued for 60 minutes at 15°C. Excess α -[³²P]-dATP was removed using a Sephadex spin column.

20 Buffers for poly(A) mRNA hybridization to Dynabeads
M-280 Streptavidin coupled with oligo(dT)₂₅

Poly(A) binding buffer:

0.5M LiCl, 10 mM Tris-Cl, pH 7.5, 1 mM EDTA, 0.1 % sodium dodecylsulphate.

Middle wash buffer:

25 0.15M LiCl, 10 mM Tris-Cl, pH 7.5, 1 mM EDTA, 0.1 % sodium dodecylsulphate.

Elution buffer: 2 mM EDTA, 0.1 % SDS. Depending on the subsequent use of the purified mRNA SDS may be omitted in the last washing step and in the elution buffer.

30

Example 6

Quantitative assay for polyadenylated mRNA present in a solution

35 mRNA from a hybridoma cell line AB₄ has been isolated by the use of magnetic beads but a method more sensitive than UV-spectrophotometry was needed to measure its concentration.

Commercially available polyA mRNA from mouse pancreas (clontech) of known concentration was suspended into the following dilutions. 50 μ l 6 x SSPE containing 2 units of RNasin and 10 mM DDT, and respectively 100 ng (0.25 pmols), 50 ng (0.12 pmols), 20 ng (50 fmols) and 10 ng (25 fmols). [The μ g/mol correlation is calculated by assuming an average length of the polyA mRNA to be 1200 bases. This gives a molecular weight of 396.000 daltons and suggests that 1 μ g mRNA is 2.5 pmols.]

10 Four similar dilutions were made from the AB₄ mRNA but of unknown concentration.

The DNA probe named RET was coupled to magnetic beads (R502) and gave a hybridization capacity of 8 pmols/mg beads of a (dA)₁₇ oligo-nucleotide.

15 0.5 mg of RET beads were added to each of the eight mixtures and the mRNA was let to hybridize to the magnetic probes for 10 minutes at room temperature. It was known from earlier experiments that more than 90% of the mRNA is hybridized in this time when such a large 20 molar excess of probes, compared to mRNA, is used (in this case greater than 20:1).

The beads were collected (aggregated) and washed once in 200 μ l 2 x SSPE at room temperature.

25 To each of the eight tubes, together with a negative control of 0.5 mg RET-bead without mRNA, was added 50 μ l of a larger premixed reaction cocktail.

The 50 μ l mixture contains:

1 Klenow buffer (50 mM NaCl, 20 mM Tris-HCl pH 7.5)
1mM EDTA
30 1 u Klenow Enzyme
1 μ Ci α -[³²P]-dTTP
100 pmols cold dTTP

The tubes were incubated at 15°C for 60 minutes on a roller machine to avoid sedimentation of beads. After 35 incubation the beads were washed twice in 200 μ l 0.2 M NaOH, 0.5 M NaCl and resuspended in 50 μ l TE-buffer (10 mM Tris-HCl, pH 7.4, 1 mM EDTA).

The amount of incorporated radioactivity was measured in a scintillation counter.

The results (as shown in Fig. 1) gave a clear linear correlation between added standard mRNA and incorporated dTTP. Two of the test samples (AB₄) were within the range of selected standard dilutions and each of them could be used to decide the actual AB₄ mRNA concentration from the standard curve in Fig. 1.

The negative control gave zero incorporation of dTTP as expected since no template was available.

Example 7

A similar set of experiments as in Example 6 but with 100 µg Dynabeads M280 streptavidin particles coupled with biotinylated oligodT₂₅ were allowed to hybridize to 100 ng, 50 ng, 20 ng and 10 ng of Promega control mRNA (~1.2 kb kanamycin mRNA containing a 30A residue polyA tail) and after two washing steps in 2 x SSPE a standard single strand cDNA synthesis (Promega protocol) was performed using reverse transcriptase and ($\alpha^{32}p$)dCTP after two washes in 0.2 M NaOH, and resuspension in 50 µl TE (100mM tris pH7.5, 10mM EDTA). The amount of incorporated radioactivity was measured in a scintillation counter with similar result as in Example 6.

Claims

1. A method for the detection and/or quantitative determination of target RNA or DNA in an analyte sample which includes the steps of:
 - a) contacting the analyte with magnetic particles carrying a single stranded 5'-attached DNA probe capable of binding to said RNA or DNA;
 - b) contacting the magnetic particles with an aqueous solution of a reverse transcriptase or polymerase in the presence of labelled nucleotides using the probe as a primer whereby labelled complementary single stranded DNA is formed if said RNA or DNA was present in said analyte; magnetically aggregating the magnetic particles onto a surface and removing said solution; and
 - c) detecting the presence or absence of said label and/or determining the amount of said label.
2. A method as claimed in claim 1 wherein the chain length of complementary single stranded DNA is limited.
3. A method as claimed in claim 2 wherein a predetermined amount of dideoxynucleotides are present at step (b) to limit chain synthesis to a predetermined average length thereby enabling the total amount of label to be correlated with the number of target nucleic acid molecules.
4. A method as claimed in any one of claims 1, 2 or 3 wherein the probe used in step (a) is oligo-dT.
5. A method as claimed in claim 2 wherein the probe binds to said DNA or RNA a predetermined distance from a chain terminating point of said DNA or RNA to enable the total amount of label to be correlated with the number of target nucleic acid molecules.

6. A method as claimed in any preceding claim wherein polymerase chain reactions (PCR) occurs between steps (a) and (b) to amplify said target RNA or DNA, primers for PCR being 5'-attached to magnetic particles.

5

7. A method according to any preceding claim wherein washing steps occur between each of steps (a), (b) and (c).

10 8. A method according to any preceding claim wherein the labelled nucleotides comprise a label selected from the group consisting of radiolabels, fluorophores, chromophores, and a low molecular weight ligand of a specific binding pair.

15

9. A method of detecting the presence of and/or amount of a microorganism in a sample wherein RNA or DNA of said microorganism is detected according to any method as claimed in any one of claims 1 to 8.

20

10. A kit for the detection and/or quantitative determination of target RNA or DNA comprising

- (a) magnetic particles carrying single stranded 5'-attached DNA probe, and one or more of the following:
- (b) a reverse transcriptase
- (c) a polymerase
- (d) labelled nucleotides
- (e) appropriate buffers.
